

Description

The ADNS-2051 is a low cost optical sensor used to implement a non-mechanical tracking engine for computer mice.

It is based on optical navigation technology, which measures changes in position by optically acquiring sequential surface images (frames) and mathematically determining the direction and magnitude of movement.

The sensor is housed in a 16-pin staggered dual inline package (DIP) that is designed for use with the HDNS-2100 Lens and HDNS-2200 Clip and HLMP-ED80 (639 nm LED illuminator source). There are no moving parts, and precision optical alignment is not required, facilitating high volume assembly.

The output format is two channel quadrature (X and Y direction) which emulates encoder phototransistors. The current X and Y information are also available in registers accessed via a serial port.

Default resolution is specified as 400 counts per inch (cpi), with rates of motion up to 14 inches per second (ips).

Resolution can also be programmed to 800 cpi.

The part is programmed via a two wire serial port, through registers.

Theory of Operation

The ADNS-2051 is based on Optical Navigation Technology. It contains an Image Acquisition System (IAS), a Digital Signal Processor (DSP), a two-channel quadrature output, and a two wire serial port.

The IAS acquires microscopic surface images via the lens and illumination system provided by the HDNS-2100, 2200, and HLMP-ED80 LED. These images are processed by the DSP to determine the direction and distance of motion. The DSP generates the Δx and Δy relative displacement values that are converted into two channel quadrature signals.

Features

- Precise optical navigation technology
- No mechanical moving parts
- Complete 2D motion sensor
- Serial interface and/or quadrature interface
- Smooth surface navigation
- Programmable frame speed up to 2300 frames per sec (fps)
- Accurate motion up to 14 ips
- 800 cpi resolution
- High reliability
- High speed motion detector
- No precision optical alignment
- Wave solderable
- Single 5.0 volt power supply
- Shutdown pin for USB suspend mode operation
- Power conservation mode during times of no movement
- On chip LED drive with regulated current
- Serial port registers
 - Programming
 - Data transfer
- 16-pin staggered dual inline package (DIP)

Applications

- Mice for desktop PCs, workstations, and portable PCs
- Trackballs
- Integrated input devices

Outline Drawing of ADNS-2051 Optical Mouse Sensor

Pinout

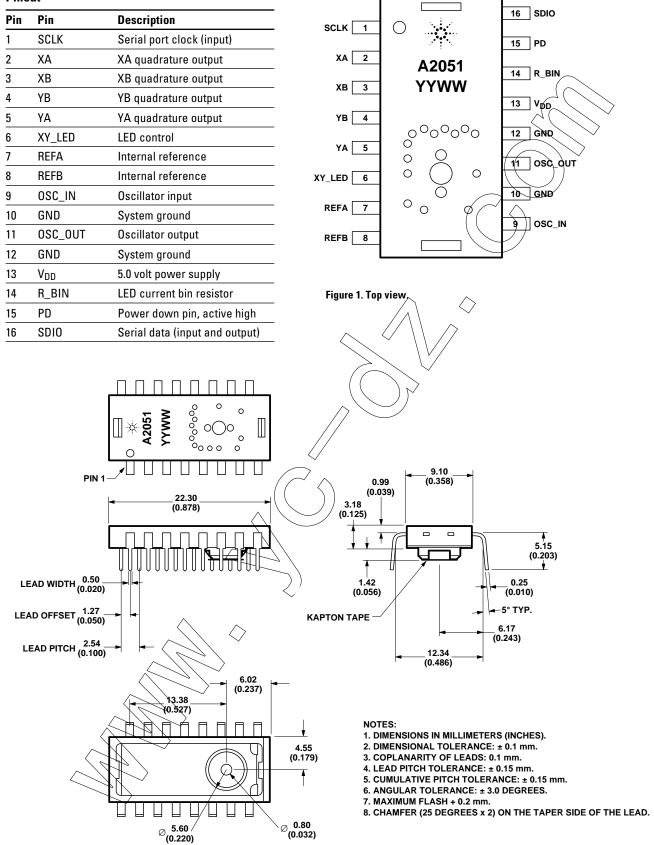

Figure 2. Package outline drawing.

Overview of Optical Mouse Sensor Assembly

2D Assembly Drawing of ADNS-2051

Figures 3 and 4, shown with HDNS-2100, HDNS-2200, and HLMP-ED80.

Agilent Technologies provides an IGES file drawing describing the base plate molding features for lens and PCB alignment.

The components interlock as they are mounted onto defined features on the base plate.

The ADNS-2051 sensor is designed for mounting on a through hole PCB, looking down. There is an aperture stop and features on the package that align to the lens (see Figure 3).

The HDNS-2100 lens provides optics for the imaging of the surface as well as illumination of the surface at the optimum angle. Features on the lens align it to the sensor, base plate, and clip with the LED. The lens also has a large round flange to provide a long creepage path for any ESD events that occur at the opening of the base plate (see Figure 4).

The HDNS-2200 clip holds the LED in relation to the lens. The LED must be inserted into the clip and the LED's leads formed prior to loading on the PCB. The clip interlocks the sensor to the lens, and through the lens to the alignment features on the base plate.

The HLMP-ED80 LED is recommended for illumination. If used with the bin table, sufficient illumination can be guaranteed.

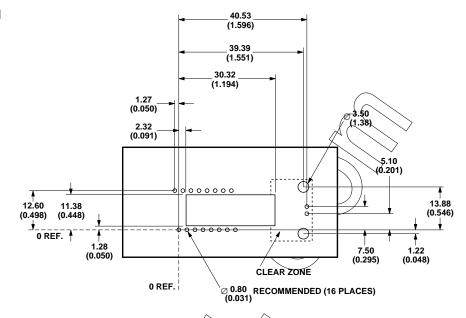

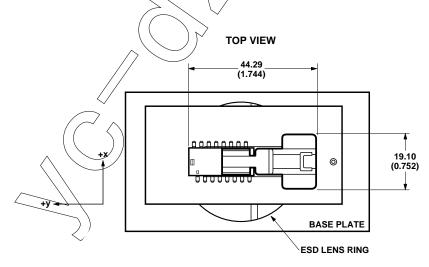

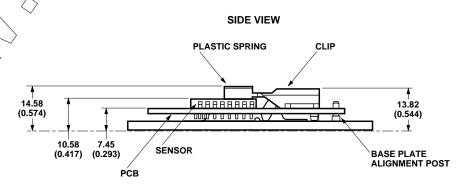

Figure 3. Recommended PCB mechanical cutouts and spacing (top view).

DIMENSIONS IN MILLIMETERS (INCHES)

DIMENSIONS IN MILLIMETERS (INCHES).

Figure 4. 2D assembly drawing of ADNS-2051 (top and side view).

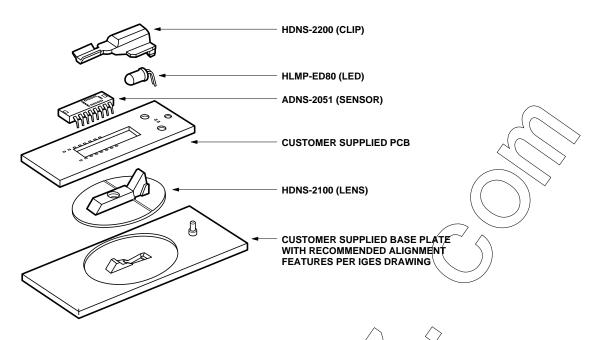

Figure 5. Exploded view drawing.

PCB Assembly Considerations

- 1. Insert the sensor and all other electrical components into PCB.
- 2. Bend the LED leads 90° and then insert the LED into the assembly clip until the snap feature locks the LED base.
- Insert the LED/clip assembly into PCB.
- 4. Wave Solder the entire assembly in a no-wash solder process utilizing solder fixture. The solder fixture is needed to protect the sensor during the solder process. The fixture should be designed to expose the sensor leads to solder while shielding the optical aperture from direct solder contact. The solder fixture is also used to

set the reference height of the sensor to the PCB top during wave soldering (Note: DO NOT remove the kapton tape during wave soldering).

- 5. Place the lens onto the base plate.
- 6. Remove the protective kapton tape from optical aperture of the sensor. Care must be taken to keep contaminants from entering the aperture. It is recommended not to place the PCB facing up during the entire mouse assembly process. The PCB should be held vertically during the kapton removal process.
- 7. Insert PCB assembly over the lens onto the base plate aligning post to retain PCB assembly. The sensor aperture ring should self-align to the lens.
- 8. The optical position reference for the PCB is set by the base plate and lens. Note that the PCB motion due to button presses must be minimized to maintain optical alignment.
- Install mouse top case. There MUST be a feature in the top case to press down onto the clip to ensure all components are interlocked to the correct vertical height.

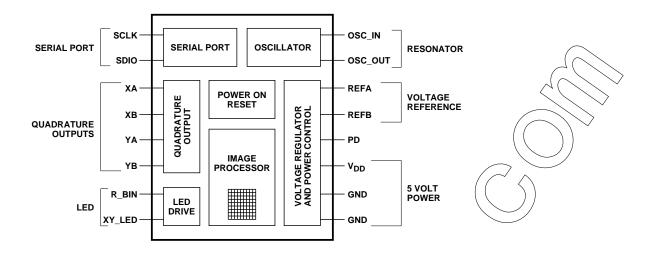

Figure 6. Block diagram of ADNS-2051 optical mouse sensor.

Design Considerations for Improving ESD Performance

The flange on the lens has been designed to increase the creepage and clearance distance for electrostatic discharge. The table on the right shows typical values assuming base plate construction per the Agilent supplied IGES file and HDNS-2100 lens flange.

Typical Dista	nce Millimeters
Creepage	/16.0
Clearance	<u>/</u> 2.1

For improved ESD performance, the lens flange can be sealed (i.e. glued) to the base plate. Note that the lens material is polycarbonate and therefore, cyanoacrylatebased adhesives or other adhesives that may damage the lens should NOT be used.

The trimmed lens, HDNS-2100#001, is not recommended for corded applications due to the ESD spec requirement.

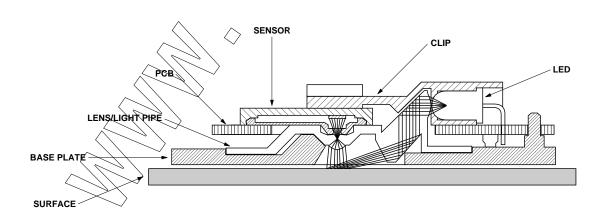

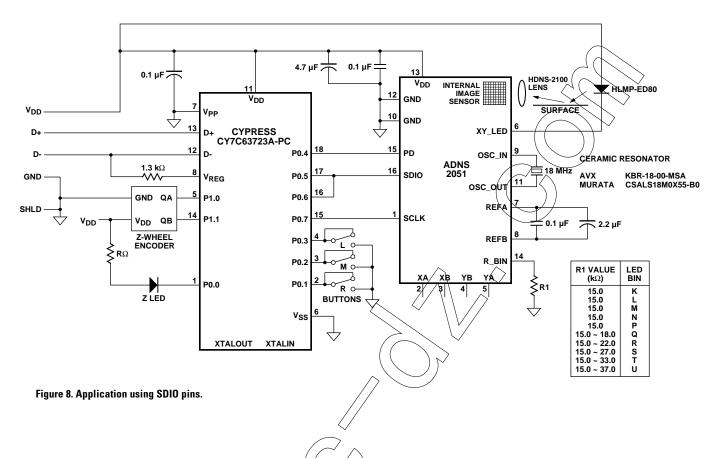

Figure 7. PCB assembly.

Recommended Typical Application using SDIO Pins

Notes on Bypass Capacitors:

- Caps for pins 7, 8 and 12, 13
 MUST have trace lengths LESS than 5 mm.
- The 0.1 μF caps must be ceramic.
- Caps should have less than
 5 nH of self inductance
- Caps should have less than
 0.2 Ω ESR

Surface mount parts are recommended.

Regulatory Requirements

- Passes FCC B and worldwide analogous emission limits when assembled into a mouse with unshielded cable and following Agilent recommendations.
- Passes EN61000-4-4/IEC801-4
 EFT tests when assembled into a mouse with unshielded cable and following Agilent recommendations.
- UL flammability level UL94 V-0.
- Provides sufficient ESD creepage/clearance distance to avoid

- discharge up to 15 kV when assembled into a mouse according to usage instructions above.
- For eye safety consideration, please refer to the technical report available on the web site, http://www.agilent.com
- The 15.0 kΩ resistor is determined by the absolute maximum rating of 50 mA for the HLMP-ED80. The other resistor values for brighter bins will guarantee good signals with reduced power.

Alternative Application using Quadrature Output Pins

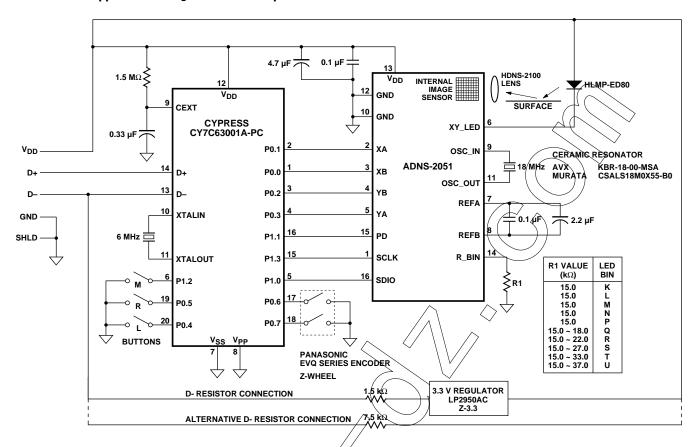

Figure 9. Application using quadrature output pins.

Notes on Bypass Capacitors:

- Caps for pins 7, 8 and 12, 13 MUST have trace lengths LESS than 5 mm.
- The $0.1 \mu F$ caps must be ceramic.
- Caps should have less than 5 nH of self inductance
- Caps should have less than $0.2 \Omega \to \mathbb{R}$

Surface mount parts are recommended.

SDIO and SCLK pins should be grounded if not used.

Absolute Maximum Ratings

PD Pin Timing

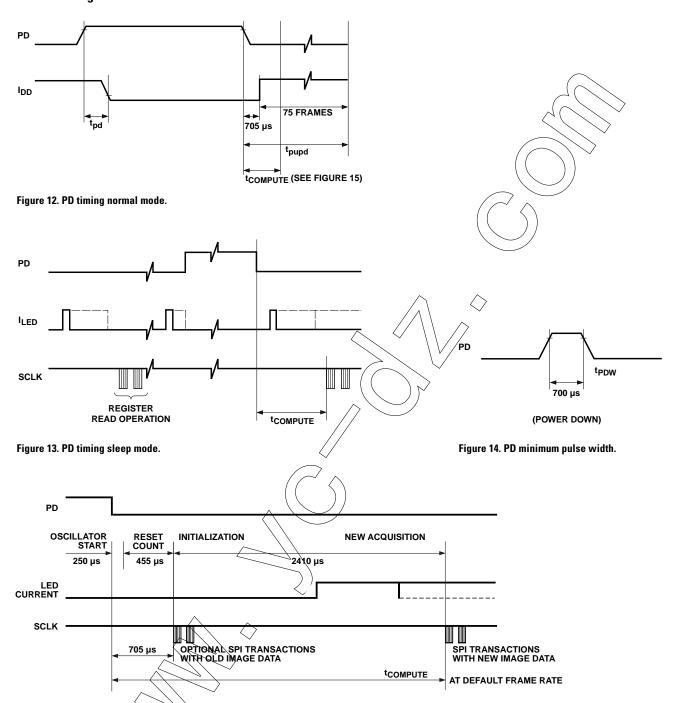

Figure 15. Detail of PD falling edge timing.

Quadrature Mode Timing

The output waveforms emulate the output from encoders. With the resolution set to $400~\rm cpi$, from one to five quadrature states can exist within one frame time. The minimum state time is $133~\mu s$. If the resolution is

800 cpi, then up to ten quadrature states can exist within a frame time. If the motion within a frame is greater than these values, the extra motion will be reported in the next frame. The following diagrams (see Figures 16, 17, and 18) show the timing

for positive X motion, to the right or positive Y motion, up. If a power down via the PD pin occurs during a transfer, the transfer will resume after PD is de-asserted. The timing for that quadrature state will be increased by the length of the PD time.

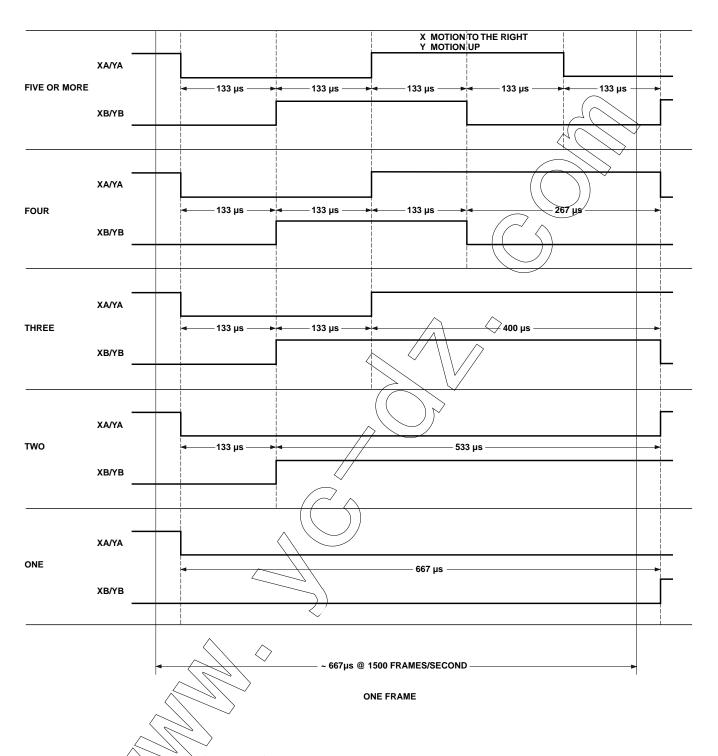

Figure 16. Quadrature states per frame (400 cpi mode).

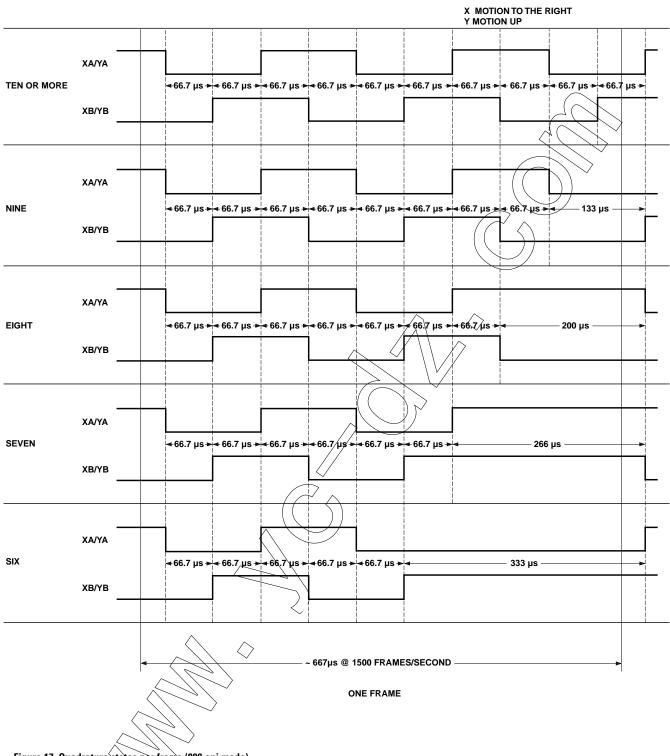

Figure 17. Quadrature states per frame (800 cpi mode).

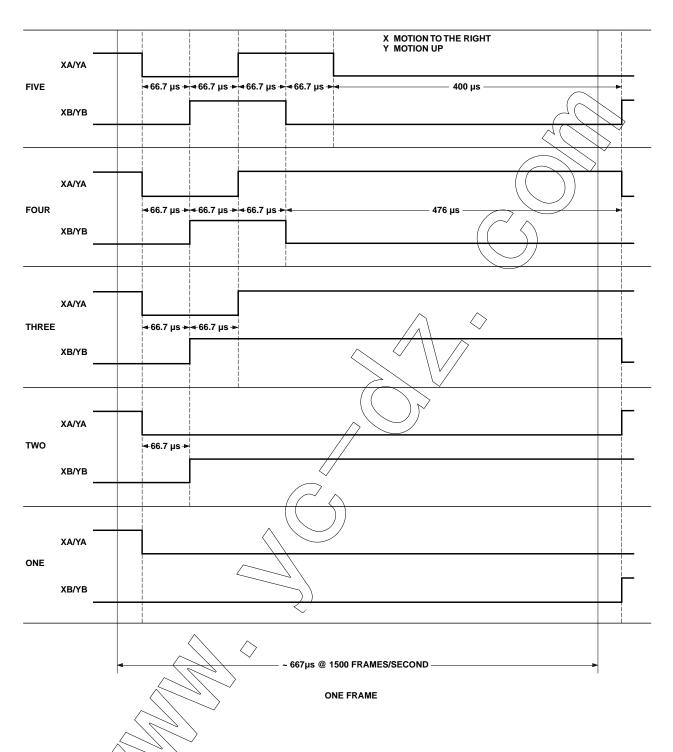

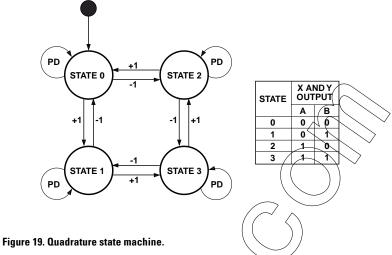

Figure 18. Quadrature states per frame (800 cpi mode).

Quadrature State Machine

The following state machine shows the states of the quadrature pins. The two things to note are that while the PD pin is asserted, the state machine is halted. Once PD is de-asserted, the state machine picks up from where it left off. State 0 is entered after a power up reset.

Quadrature Output Waveform The two channel quadrature outputs are 5.0 volt CMOS outputs. The Δx count is used to generate the XA and XB signals, and Δy count is used for the YA and YB signals. Figure 24. Typical resolution vs. z (black copy and LED variation).^[2,3]

Note:

- The ADNS-2051 is designed for optimal performance when used with the HLMP-ED80 (red LED 639 nm). For use with other LED colors (i.e., blue, green), please consult factory. When using alternate LEDs, there may also be performance degradation and additional eye safety considerations.
- 2. Z = Distance from Lens Reference plane to Surface.
- 3. DOF = Depth of Field.

Synchronous Serial Port

The synchronous serial port is used to set and read parameters in the ADNS-2051, and can be used to read out the motion information instead of the quadrature data pins.

The port is a two wire, half duplex port. The host micro-controller always initiates communication; the ADNS-2051 never initiates data transfers.

SCLK: The serial port clock. It is always generated by the master (the microcontroller).

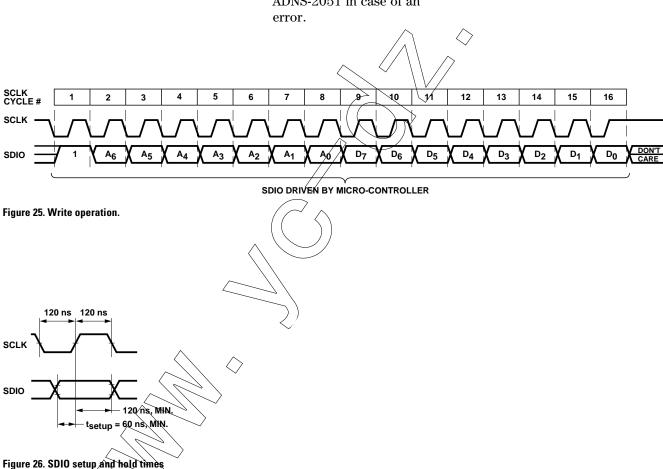

SDIO: The data line.

PD:

A third line is sometimes involved. PD (Power Down) is usually used to place the ADNS-2051 in a low power mode to meet USB suspend specification. PD can also be used to force re-synchronization between the micro-controller and the ADNS-2051 in case of an

Write Operation

Write operations, where data is going from the micro-controller to the ADNS-2051, is always initiated by the micro-controller and consists of two bytes. The first byte contains the address (seven bits) and has a "1" as its MSB to indicate data direction. The second byte contains the data. The transfer is synchronized by SCLK. The micro-controller changes SDIO on falling edges of SCLK. The ADNS-2051 reads SDIO on rising edges of SCLK.

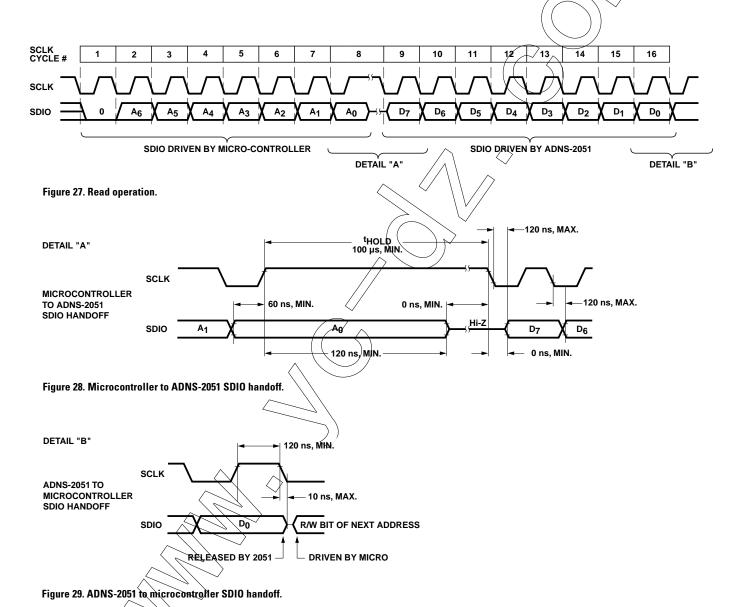

SCLK pulse width.

Read Operation

A read operation, which means that data is going from the ADNS-2051 to the microcontroller, is always initiated by the micro-controller and consists of two bytes. The first byte contains the address, is written by the micro-controller, and has a "0" as its MSB to indicate data

direction. The second byte contains the data and is driven by the ADNS-2051. The transfer is synchronized by SCLK. SDIO is changed on falling edges of SCLK and read on every rising edge of SCLK. The micro-controller must go to a high Z state after the last address data bit. The ADNS-2051 will go to the high Z state after

the last data bit (see detail "B" in Figure 28). One other thing to note during a read operation is that SCLK will need to be delayed after the last address data bit to ensure that the ADNS-2051 has at least 100 µs to prepare the requested data. This is shown in the timing diagrams below.

Note:

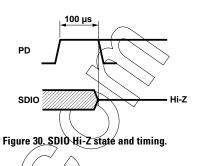

The 120 ns high state of SCLK is the minimum data hold time of the ADNS-2051. Since the falling edge of SCLK is actually the start of the next read or write command, the ADNS-2051 will hold the state of D_0 on the SDIO line until the falling edge of SCLK. In both write and read operations, SCLK is driven by the micro-controller.

Serial port communications is not allowed while PD (power down) is high. See "**Error Detection and Recovery**" regarding re-synchronizing via PD.

Forcing the SDIO Line to the Hi-Z State

There are times when the SDIO line from the ADNS-2051 should be in the Hi-Z state. If the microprocessor has completed a write to the ADNS-2051, the SDIO line is Hi-Z, since the SDIO pin is still configured as an input. However, if the last operation from the microprocessor was a read, the ADNS-2051 will hold the D0 state on SDIO until a falling edge of SCLK.

To place the SDIO pin into the Hi-Z state, raise the PD pin for $100~\mu s$ (min). The PD pin can stay high, with the ADNS-2051 in the shutdown state, or the PD pin can be lowered, returning the ADNS-2051 to normal operation. The SDIO line will now be in the Hi-Z state.

Required timing between Read and Write Commands (tsxx)

There are minimum timing requirements between read and write commands on the serial port.

If the rising edge of the SCLK for the last data bit of the second write command occurs before the 100 microsecond required delay, then the first write command may not complete correctly.

If the rising edge of SCLK for the last address bit of the read command occurs before the 100 microsecond required delay, then the write command may not complete correctly.

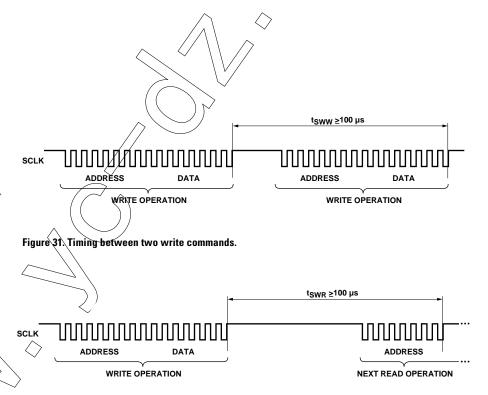

Figure 32. Timing between write and read commands.

The falling edge of SCLK for the first address bit of either the read or write command must be at least 120 ns after the last SCLK rising edge of the last data bit of the previous read operation.

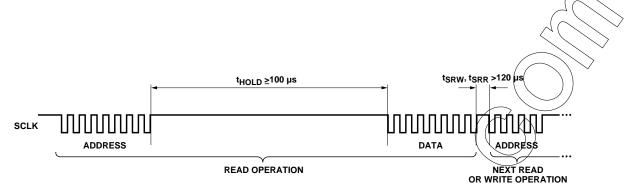

Figure 33. Timing between read and either write or subsequent read commands.

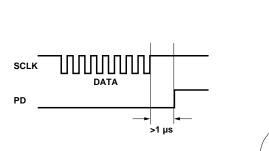

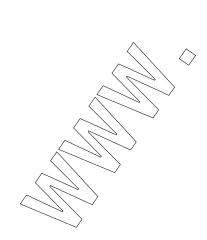

Figure 34. Timing between SCLK and PD rising edge.

Error Detection and Recovery

- 1. The ADNS-2051 and the micro-controller might get out of synchronization due to ESD events, power supply droops or micro-controller firmware flaws. In such a case, the micro-controller should raise PD for 100 μs. The ADNS-2051 will reset the serial port but will not reset the registers and be prepared for the beginning of a new transmission.
- 2. The ADNS-2051 has a transaction timer for the serial port. If the sixteenth SCLK rising edge is spaced more than approximately 0.9 seconds from the first SCLK edge of the current transaction, the serial port will reset.
- 3. Invalid addresses:
 - Writing to an invalid address will have no effect.
 Reading from an invalid address will return all zeros.
- 4. Collision detection on SDIO
 - The only time that the ADNS-2051 drives the SDIO line is during a READ operation. To avoid data collisions, the microcontroller should relinquish SDIO before the falling edge of SCLK after the last

- address bit. The ADNS-2051 begins to drive SDIO after the next rising edge of SCLK. The ADNS-2051 relinquishes SDIO within 120 ns of the falling SCLK edge after the last data bit. The microcontroller can begin driving SDIO any time after that. In order to maintain low power consumption in normal operation or when the PD pin is pulled high, the micro-controller should not leave SDIO floating until the next transmission (although that will not cause any communication difficulties).
- 5. In case of synchronization failure, both the ADNS-2051 and the micro-controller may drive SDIO. The ADNS-2051 can withstand 30 mA of short circuit current and will with stand infinite duration short circuit conditions.
- 6. Termination of a transmission by the micro-controller may sometimes be required (for example, due to a USB suspend interrupt during a read operation). To accomplish this the micro-controller should raise PD. The ADNS-2051 will not write to any register and will reset the serial port (but

- nothing else) and be prepared for the beginning of future transmissions after PD goes low.
- 7. The micro-controller can verify success of write operations by issuing a read command to the same address and comparing written data to read data.
- 8. The micro-controller can verify the synchronization of the serial port by periodically reading the product ID register.

Notes on Power up and the Serial Port

The sequence in which V_{DD}, PD, SCLK, and SDIO are set during powerup can affect the operation of the serial port. The diagram below shows what can happen shortly after powerup when the microprocessor tries to read data from the serial port.

This diagram shows the V_{DD} rising to valid levels, at some point the microcontroller starts its program, sets the SCLK and SDIO lines to be outputs, and sets them high. It then waits to ensure that the ADNS-2051 has powered up and is ready to communicate. The microprocessor then tries to read from location 0x00, Product ID,

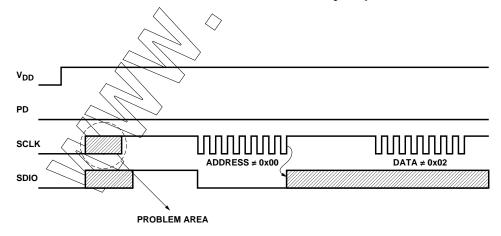

Figure 35. Power up serial port watchdog timer sequence.

and is expecting a value of 0x02. If it receives this value, it then knows that the communication to the ADNS-2051 is operational.

The problem occurs if the ADNS-2051 powers up before the microprocessor sets the SCLK and SDIO lines to be outputs and high. The ADNS-2051 sees the raising of the SCLK as a valid rising edge, and clocks in the state of the SDIO as the first bit of the address (sets either a read or a write depending upon the state).

In the case of SDIO low, then a read operation has started. When the microprocessor begins to actually send the address, the ADNS-2051 already has the first bit of an address. When the seventh bit is sent by the micro, the ADNS-2051 has a valid address, and drives the SDIO line high within 120 ns (see detail "A" in Figure 27 and Figure 28). This results in a bus fight for SDIO. Since the address is wrong, the data sent back will be incorrect.

In the case of SDIO high, a write operation is started. The address and data are out of synchronization, and the wrong data will be written to the wrong address.

Two Solutions

There are two different ways to solve the problem, waiting for the serial port watchdog timer to time out, or using the PD line to reset the serial port.

1. Serial Port Watchdog Timer Timeout

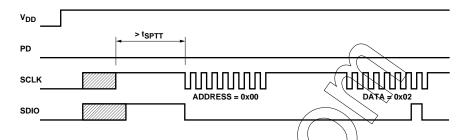

Figure 36. Power up serial port watchdog timer sequence

If the microprocessor waits at least t_{SPTT} from V_{DD} valid, it will ensure that the ADNS-2051 has powered up and the watchdog timer has timed out. This assumes that the microprocessor and the ADNS-2051 share the same power supply If not, then the microprocessor must wait t_{SPTT} from ADNS-2051 V_{DD} valid. Then when the SCLK toggles for the address, the ADNS-2051 will be in sync-with the microprocessor.

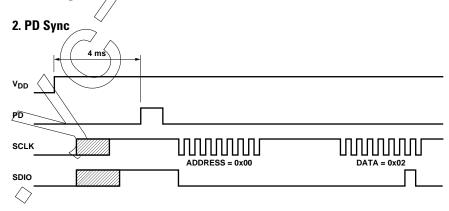

Figure 37. Power up serial port PD sync sequence.

The PD line can be used to resync the serial port. If the microprocessor waits for 4 ms from V_{DD} valid, and then outputs a valid PD pulse (see Figure 15), then the serial port will be ready for data.

Resync Note

If the microprocessor and the ADNS-2051 get out of sync, then the data either written or read from the registers will be incorrect. An easy way to solve this is to output a PD pulse to resync the parts after an incorrect read.

SPI communication code for the Cypress CY7C63000 or CY7C63001

(Please consult factory for the CY7C63722 or CY7C63723 codes)

```

Registers

The ADNS-2051 can be programmed through registers, via the serial port, and configuration and motion data can be read from these registers.

Address	Register
0x00	Product_ID
0x01	Revision_ID
0x02	Motion
0x03	Delta_X
0x04	Delta_Y
0x05	SQUAL

Address	Register
0x06	Average_Pixel
0x07	Maximum_Pixel
0x08	Reserved
0x09	Reserved
0x0a	Configuration_bits
0x0b	Reserved

Address	Register
0x0c	Data Out Lower
0x0d	Data_Qut_Upper
0x0e	Shutter_Lower
0x0f	Shutter_Upper
0x10	Frame_Period_Lower
0x11	Frame_Period_Upper

Product_ID Address: 0x00 Access: Read Reset Value: 0x02 Bit 7 6 5 3 1 2 PID₇ PID_6 PID_5 PID_4 PID_3 PID₂ PID₁ Field

Data Type: Eight bit number with the product identifier.

USAGE: The value in this register does not change, it can be used to verify that the serial communications link is OK.

Revision_ID					ress: 0x0	()		
Access: Rea	d			Res	et Value:	0xNN		
Bit	7	6	5	4	3	_2 /	1	0
Field	RID ₇	RID ₆	RID ₅	RID ₄	RND ₃	RID ₂	RID ₁	RID ₀

Data Type: Eight bit number with current revision of the IC.

USAGE: NN is a value between 00 and FF which represent the current design revision of the device.

Motion Address: 0x02 Access: Read Reset Value: 0x00 Bit 5 4 3 2 1 0 **FOM** Field Reserved **FAULT OVFY OVFX** Reserved Reserved **RES**

Data Type: Bit field

USAGE: Register 0x02 allows the user to determine if motion has occurred since the last time it was read. If so, then the user should read registers 0x03 and 0x04 to get the accumulated motion. It also tells if the motion buffers have overflowed and whether or not an LED fault occurred since the last reading. The current resolution is also shown.

Motion since last report or PD 0 = No motion 1 = Motion occurred, data ready for reading in Delta_X and Delta_Y registers
Reserved for future
LED Fault detected – set when R_BIN is too low or too high, shorts to V _{DD} or Ground 0 = No fault 1 = Fault detected
Motion overflow Y, Δ Y buffer has overflowed since last report $0 = \mathbf{No}$ overflow $1 = 0$ overflow has occurred
Motion overflow X, Δ X buffer has overflowed since last report 0 = No overflow 1 = Overflow has occurred
Reserved for future
Reserved for future
Resolution in counts per inch 0 = 400 1 = 800

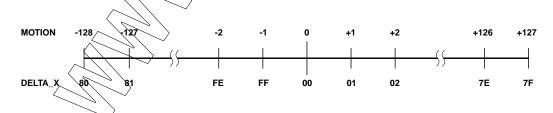

Notes for Motion:

- 1. Reading this register freezes the Delta_X and Delta_Y register values. Read this register before reading the Delta_X and Delta_Y registers. If Delta_X and Delta_Y are not read before the motion register is read a second time, the data in Delta_X and Delta_Y will be lost.
- 2. Agilent RECOMMENDS that registers 0x02, 0x03 and 0x04 be read sequentially.
- 3. Internal buffers can accumulate more than eight bits of motion for X or Y. If either one of the internal buffers overflows, then absolute path data is lost, and the OVFX or OVFY bit is set. These bits (OVFX and OVFY) are cleared once some motion has been read from the Delta_X and Delta_Y registers, and if the buffers are not at full scale. Since more data is present in the buffers, the cycle of reading the Motion, Delta_X and Delta_Y registers should be repeated until the motion bit (MOT) is cleared. Until MOT is cleared, either the Delta_X or Delta_Y registers will read either positive or negative full scale. If the motion register has not been read for a long time, at 400 cpi it may take up to 16 read cycles to clear the buffers, at 800 cpi, up to 32 cycles.
- 4. FAULT is a sticky bit that is cleared by reading the Motion register. It signifies that an LED fault has occurred since the last time the motion register was read. Once an LED fault has cleared, the hardware will drive the LED normally.

Delta_X Address: 0x03								
Access: Read Reset Value: 0x00								
Bit	7	6	5	4	3	2	1	0
Field	X ₇	X ₆	X ₅	X ₄	X ₃	X ₂	X ₁	X ₀

Data Type: Eight bit 2's complement number.

USAGE: X movement is counts since last report. Absolute value is determined by resolution. Reading clears the register.

Delta_Y

Address: 0x04

Access: Rea	d
Bit	

Field

Kes	et value:	UXUU		
4	3	2	1	0
Yμ	Υ ₂	Υ ₂	Y ₁	Υn

Data Type: Eight bit 2's complement number.

6

 Y_6

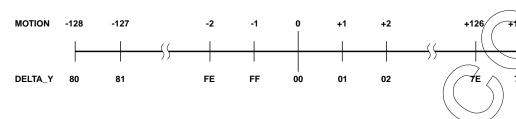

5

Y₅

7

Y₇

USAGE: Y movement is counts since last report. Absolute value is determined by resolution. Reading clears the register.

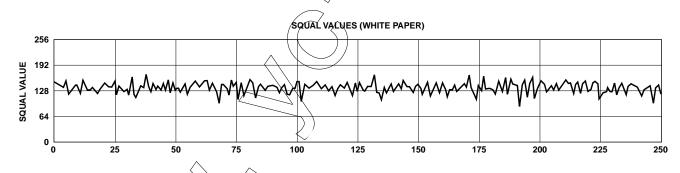

Surface_Quality

Address: 0x05

Access: Rea		Rese	et Value:	0x00				
Bit	7	6	5	4	3	2	1	9
Field	SQ ₇	SQ_6	SQ_5	SQ ₄	SO_3	SQ_2	SQ ₁	SQ ₀

Data Type: Eight bit number.

USAGE: SQUAL is a measure of the number of features visible by the sensor is the current frame. The maximum value is 255. Since small changes in the current frame can result in changes in SQUAL, variations in SQUAL when looking at a surface are expected. The graph below shows 250 sequentially acquired SQUAL values, while a sensor was moved slowly over white paper. SQUAL is nearly equal to zero, if there is no surface below the sensor.

The focus point is important and could affect the squal value, the graph below showing another setup with various z-height. The graph clearly shows that the squal count is dependent on focus distance.

Note:

This graph is obtained by getting multiple readings over different heights.

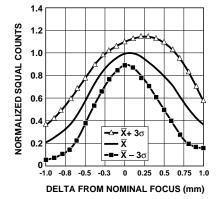

Figure 38. Typical mean squal vs. Z (white paper).

Average_Pixel

Field

Address: 0x06

 AP_3

 AP_2

Access:	Read

s: Rea <u>d Reset Value: 0x00</u>							
Bit	7	6	5	4	3	2

Maximum_Pixel

Address: 0x07

iviaxiiiiuiii_r	IVEI	Auu1633. 0x07					
Access: Rea	Reset Value: 0x00						
Bit	7	6	5	4	3	2//	7
Field	n	n	MP	MΡ₄	MPa	MP ₂	Γ

Data Type: Six bit number.

USAGE: Maximum Pixel value in current frame. Minimum value = 0, maximum value = 63. The maximum pixel value can be adjusted every frame. Shown below is a graph of 250 sequentially acquired maximum pixel values, while the sensor was moved slowly over white paper.

Reserved

Address: 0x09

Data_Out_Lower Address: 0x0c								
Access: Read Re				Res	et Value:	undefin	ed	
Bit	6	5	4	3	2	1	0	
Field	D0 ₇	D0 ₆	DO ₅	DO ₄	DO ₃	D02	DO ₁	DO_0

Data_Out_Upper Access: Read					Address: 0x0d Reset Value: undefined			
Bit	7	7 6 5 4 3 2 1						
Field	DO ₁₃	DO ₁₂	DO ₁₁	DO ₁₀	DO ₉	D08		

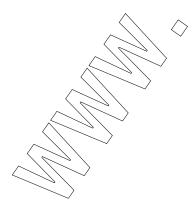

Data Type: Sixteen bit word.

USAGE: Data can be written to these registers from the system self test, or the pixel dump command. The data can be read out 0x0d, or 0x0d first, then 0x0c.

	Data_Out_Upper	Data_Out_Lower / Note
System test result 1:	FE	D4 One of two results returned. These
System test result 2:	4D	values are subject to change with each device design revision.
Pixel Dump command	Pixel Address	Pixel Data (Lower 6) bits)

Once the pixel dump command is given, the sensor writes the address and the value for the first pixel into the Data_Out_Upper and Data_Out_Lower registers. The MSB of Data_Out_Lower is the status bit for the data. If the bit is high, the data are NOT valid. Once the MSB is low, the data for that particular read are valid and should be saved. The pixel address and data will then be incremented on the next frame. Once the pixel dump is complete, the PixDump bit in register 0x0a should be set to zero. To obtain an accurate image, the LED needs to be turned on by changing the sleep mode of the configuration register 0x0a to always awake.

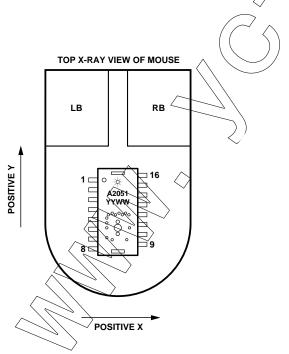

Figure 39. Directions are for a complete mouse, with the HDNS-2100 lens.

Pixel Dump Pictures

The following images (Figure 40) are the output of the pixel dump command. The data ranges from zero for complete black, to 63 for complete white. An internal AGC circuit adjusts the shutter value to keep the brightest feature (max. pixel) in the mid 50s.

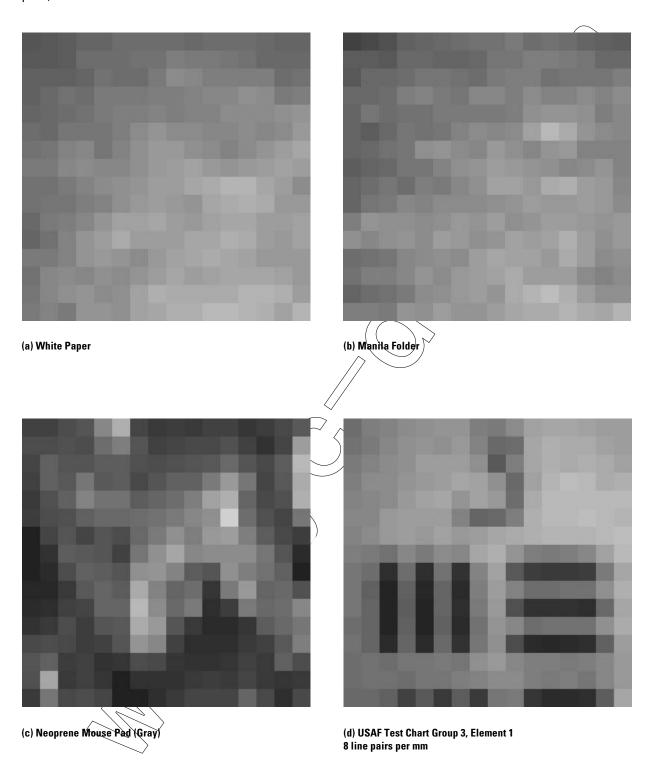

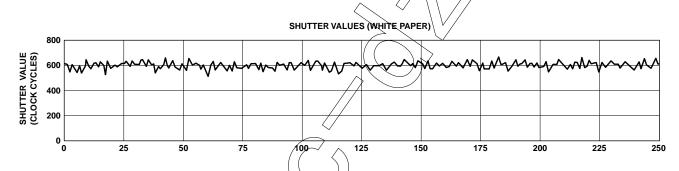

Figure 40. Pixel dump pictures.

Shutter_Low	er er		Address: 0x0e					
Access: Rea	Reset Value: 0x64							
Bit	7	6	5	4	3	2	1	0
Field	S ₇	S ₆	S ₅	S ₄	S ₃	S ₂	S ₁	S ₀

Shutter_Upp Access: Rea		Address: 0x0f Reset Value: 0x00						
Bit	7	6	5	4	3	2	1	0
Field	S ₁₅	S ₁₄	S ₁₃	S ₁₂	S ₁₁	S ₁₀	S ₉	S ₈

Data Type: Sixteen bit word.

USAGE: Units are clock cycles; default value is 64. Read Shutter_Upper first, then Shutter_Lower. They should be read consecutively. The shutter is adjusted to keep the average and maximum pixel values within normal operating ranges. The shutter value can be adjusted to a new value on every frame. When the shutter adjusts, it changes by ±1/16 of the current value. Shown below is a graph of 250 sequentially acquired shutter values, while the sensor was moved slowly over white paper.

The focus point is important and could affect the shutter value. The graph below shows another setup with various z-height. This graph clearly shows that the shutter value is dependent on focus distance.

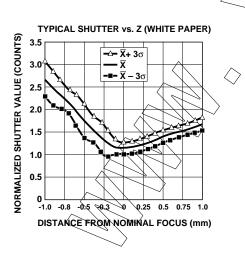

Figure 41. Typical shutter vs. Z (white paper).

Note: This graph shows average readings over different heights.

The maximum value of the shutter is dependent upon the frame rate and clock frequency. The formula for the maximum shutter value is:

Max. Shutter Value =
$$\frac{\text{Clock Frequency}}{\text{Frame Rate}}$$
 -2816

For a clock frequency of $18\,\mathrm{MHz}$, the following table shows the maximum shutter value. $1\,\mathrm{clock}$ cycle is $55.56\,\mathrm{nsec}$.

	Max Shutter	•	Shutter	
Frames/second	Decimal	Hex	Upper	Lower
2300	5010	0x1392	13	92
2000	6184	0x1828	18	28
1500	9184	0x23E0	23	E0
1000	15184	0x3B50	3B	50
500	33184	0x81A0	81	A0

Frame_Perio Access: Rea	_	er				\			
Bit	7	6	5	4	3	2	(1	∀ o\	/
Field	FP ₇	FP ₆	FP ₅	FP ₄	FP ₃	FP ₂	FP	FP ₀	T

Frame_Perio Access: Rea			ress: 0x1 et Value:	/	>	<i>))</i>		
Bit	7	6	5	4	3	2/	1	0
Field	FP ₁₅	FP ₁₄	FP ₁₃	FP ₁₂	FP ₁₁	FP 10	FP ₉	FP ₈

Data Type: Sixteen bit 2's complement word.

USAGE: The frame period counter counts up until it overflows. Units are clock cycles. The formula is:

 $\frac{\text{Clock Rate}}{\text{Frame Rate}} = \text{Counts (decimal)} \rightarrow \text{Counts (hex)} \rightarrow \text{Counts (2's complement hex)}$

For an 18 MHz clock, here are the Frame_Period values for popular frame rates.

	Counts	$\overline{}$	\bigcirc	Frame_F	Period
Frames/secon	d Decimal	Hex	2's Comp	Upper	Lower
2300*	7826	0x1E92	0xE16E	E1	6E
2000*	9000	0x2328	0xDCD8	DC	D8
1500	12000	0x2EE0	0xD120	D1	20
1000	18000	0x4650	0xB9B0	B9	В0
500	36000	0x8CA0	0x7360	73	60

← Default Frame Time

← Minimum Frame Time

*Note:

To optimize tracking performance on dark surfaces, it is recommended that an adaptive frame rate based on shutter value be implemented, for frame rates greater than 1500. Changing the frame rate results in changes in the maximum speed, acceleration limits, and dark surface performance.

To read from the registers, read Frame_Period_Upper first followed by Frame_Period_Lower. To write to the registers, write Frame_Period_Lower first followed by Frame_Period_Upper.

IC Register State after Reset (power up or setting bit 7, register 0x0a)

Ordering Information

Specify part number as follows:

ADNS-2051 = Sensor IC in a 16-pin staggered DIP, 20 per tube.

ADNB-2050 = Sensor IC and HDNS-2100 round lens bundle kit, 1000 pc incremental

ADNB-2051 = Sensor IC and HDNS-2100#001 Round lens bundle kit, 1000 pc incremental

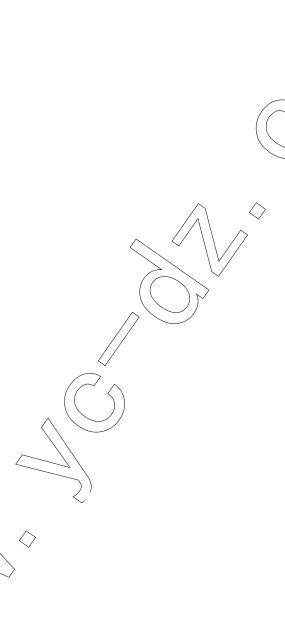

HDNS-2100 = Round Optical Mouse Lens

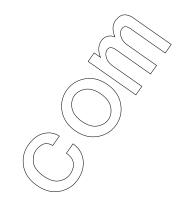

HDNS-2100#001 = Trimmed Optical Mouse Lens

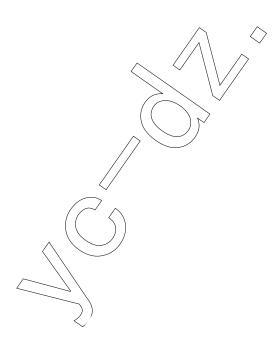

HDNS-2200 = LED Assembly Clip (Black)

HDNS-2200#001 = LED Assembly Clip (Clear)

HLMP-ED80 = LED
